

# Verifiability index as a function of methodological defect intensity

Data leakage (T) and data corruption (D) nullify the index already at minimum intensity — the veto is triggered.  
False explanation (F) and domain-logic inversion (C) reduce the index monotonically.

Intensity levels of different defects are defined in different units ( $\rho$ ,  $\eta$ , sample fraction, noise multiplier), therefore intensity is rescaled as a fraction of the maximum level tested.
